

## Program Symposium TRENDS IN THEORY 2022

Thursday, May 19

09:30 – 10:50 Registration, coffee/tea

10:50 – 11:00 Opening Remarks **Rembert Duine (UU)**  
Director of the DRSTP

---

Session Chair: Frank Saueressig (RU)

11:00 – 11:50 **Clélia de Mulatier (UL)**  
*Identifying communities in binary data with spin models: when simple matters*

Finding the model that best captures patterns hidden within noisy data is a central problem in science. In this context, the Ising model has been widely used to infer pairwise patterns in binary data. In recent years, attention has been brought to high order patterns of data and the question of how to detect them. We will discuss the use of (classical) spin models with interactions of order higher than pairwise to extract such patterns in binary data, and why this problem is challenging. By analyzing the information theoretic complexity of spin models, we will see that, despite their appearance, models with high order interactions are not necessarily more complex than pairwise models. Finally, we will focus on the family of spin models with minimal complexity and see that they can be used to uncover community structures hidden in data. This approach opens up new ways to analyze high dimensional data.

11:50 – 12:40 **Farshid Jafarpour (UU)**  
*Effects of Noise and Correlations in Bacterial Populations Dynamics*

Genetically identical bacterial cells, even in identical environments, exhibit significant variability in their phenotypic behavior such as their growth rates, division sizes, and generation times. With recent advances in single-cell technologies, we now can measure not only the distributions of these quantities but also the correlations between these variables both within and across generations. These statistical descriptions have paved the way for more accurate models of cellular growth and division. In this talk, I will discuss how the details of these new phenomenological models, such as the distributions of single-cell growth rates and the mechanism of cell-size control, affect various population-level quantities.

12:45 – 13:45 Lunch

---

Session Chair: Alicia Castro (RU)

13:45 – 14:35 **Ana Achucarro (UL)**  
*The Handmade Tail, and other (multifield inflation) stories*

Cosmic inflation gives a (quantum) explanation for the tiny, primordial density fluctuations that seeded the distribution of matter and galaxies in the Universe. If this explanation is correct, many properties of the quantum fields and particle interactions at the time of the Big Bang are still imprinted today on the statistics of the density fluctuations, and can be extracted from cosmological observations. I will discuss how to turn the Universe into the ultimate collider to do "particle physics in the sky" at the earliest moments, a fraction of a second away from the Big Bang.

## Thursday, May 19

---

14:35 – 15:40      1-Minute Poster Presentations I (odd numbers)      Session Chair: Jaco ter Hoeve (VU)

15:40 – 17:00      Poster Session I (odd numbers)

17:00 – 17:50      **Ben Freivogel (UvA)**  
*Wormholes: from science fiction to science*

In the past 5 years, traversable wormholes have moved from the realm of science fiction to science. I will describe what types of traversable wormholes can exist in our universe. I will also describe how wormholes have allowed us to calculate quantum gravity effects, partially resolving the black hole information problem, concluding with some open questions.

17:50 – 18:15      Break

18:15 – 20:15      Dinner

---

Session Chair: Frank Saueressig

20:15 – 21:15      **Evening Program - Panel discussion**  
*Sailing towards new Horizons - Your vision of Dutch Theoretical Physics in 2030*

**Panel members:** Jan de Boer (UvA, NWO)  
Remko Achten (NWO)  
Stan Bentvelsen (Nikhef)  
Renate Loll (RU)  
Carlo Beenakker (Leiden)

21:15 –      Drinks and discussion

**Friday, May 20**

08:00 – 09:00 Breakfast

---

Session Chair: Tom O'Brien (UL)

09:00 – 09:50 **Eliska Greplova (TU Delft)**  
*Title: Quantum Matter and the Multiverse of Engineered Topology*

The field of condensed matter physics is currently being transformed by a series of exciting theoretical discoveries of intriguing properties of quantum materials and remarkable experimental progress that allows us to test the novel theories contemporaneously. In this talk, I will illustrate this condensed matter renaissance with two examples that also connect condensed matter to the two emerging fields of artificial intelligence and quantum computing. First, I will discuss a top-down example that considers solving existing models with the aid of artificial intelligence tools. In a second, bottom-up approach, I will discuss on-chip engineering of topological features using scalable quantum computing building blocs.

09:50 – 10:40 **Melissa van Beekveld (Oxford/Nikhef)**  
*Frontiers of parton-shower accuracy*

Monte Carlo generators are an essential tool to understand the physics of high-energy particle collisions. Their core is represented by parton-shower algorithms, which account for the radiation of soft and collinear partons. The formal accuracy of parton-shower algorithms was for long unknown, limiting the assessment of theoretical uncertainties when using these tools. In this talk I will discuss the criteria introduced by the PanScales collaboration to determine the accuracy of showers. I will present the first family of showers for hadronic particle collisions whose accuracy exceeds that of standard showers.

10:40 – 11:45 1-Minute Poster Presentations II (even numbers) Session Chair: Ludwig Hoffmann (UL)

11:45 – 13:00 Poster Session II (even numbers)

13:05 – 14:00 Lunch

---

Session Chair: Alejandra Castro (UvA)

14:00 – 14:50 **Jonas Helsen (QuSoft)**  
*Random quantum circuits: a Drosophila fly for quantum computation*

In this talk I will give a whirlwind tour of (theoretical) quantum computation, through the lens of random quantum circuits. We will address the benchmarking of quantum systems, efficient quantum classical interfaces (often called "shadows"), and quantum supremacy experiments. Through these examples I hope to illustrate the utility of random quantum circuits as a toy model for general quantum computations, for which we can make rigorous claims. I will also discuss some of the fascinating mathematical properties of random quantum circuits, and highlight what we don't yet know (and would like to know) about them.

14:50 – 15:40      **Badri Krishnan (RU)**  
*The simplicity of binary black hole mergers*

Before the first successful numerical simulations of binary black hole mergers in 2005, it was considered plausible that the gravitational wave signal could have complicated modulations and even be chaotic. After all, general relativity is a non-linear theory and these non-linearities are especially important near the merger. However, the reality is that the signals are so far seen to be rather simple. This does not mean that the signals are trivial, rather that the complications due to e.g. precession, eccentricity etc. are contained in the deviations from a simple underlying model. In this talk, I will propose a reason for this simplicity based on the framework of "singularity theory" developed by Arnold, Zeeman and Thom in the 1960s. We shall see that binary black hole mergers are similar to other common observed physical phenomena such as caustics and rainbows in optics, and this theory provides hints for deeper mathematical structures in binary black hole dynamics.

15:40 – 15:50      Poster Prize Ceremony  
**Jury members:**  
Tomislav Prokopec (UU)  
Timothy Budd (RU)  
Susanne Westhoff (Ruprecht Karls Universität Heidelberg)  
Clélia de Mulatier (UL)

15:50 – 16:00      Closing Remarks **Rembert Duine (UU)**  
Director of the DRSTP

---
